Vol. 10, No. 41

## Provisional Information on Selected Notifiable Diseases in the United States and on Deaths in Selected Cities for Week Ended October 14, 1961

Poliomyelitis — There has been a sharp drop in the number of poliomyelitis cases reported for the current week ending October 14. A total of 35 cases, 20 paralytic, was reported. This compares to the 68 cases, including 45 paralytic, which were reported during the previous week.

The comparative low incidence during 1961 is demonstrated in the tabulation. The number of paralytic cases through the 41st week in 1961 is 37% of the number reported last year.

### Polio (Cumulated Weekly) Through the 41st Week For Past Five Years

	1961	1960	1959	1958	1957
Paralytic	654	1752	4515	2156	1777
Total	1020	2540	6956	4454	5273

One more paralytic case with onset on October 4, has been reported from Newberry County, South Carolina. Twenty cases have been reported thus far this year, 15 of which have occurred since September 1. There have been

CURRENT U.S. POLIO INCIDENCE
COMPARED WITH YEARS 1955-1960, April - December, by week

PROVISIONAL DATA SUPPLIED BY NATIONAL OFFICE OF VITAL STATISTICS

six isolations of Type III poliovirus. A mass vaccination campaign using Type III oral poliovaccine was begun on Thursday, October 19.

Two of the four paralytic cases reported from New York are related to the Syracuse outbreak but do not have recent onsets. There have been 76 paralytic cases in the tri-county area comprising Onondaga, Madison, and Oneida Counties. The most recent case experienced an onset of disease on September 24.

In Pennsylvania, two of the three paralytic cases reported are from Erie County. There are now four paralytic cases that have occurred in Erie County and a mass immunization program with inactivated vaccine is underway. The current cases were both unvaccinated school age children with onsets on September 22 and October 1.

Only one nonparalytic case has been reported from the cluster of cases in Windsor County, Vermont and adjoining Sullivan County, New Hampshire. Nine cases have been reported from these counties of which only four are paralytic. Type I poliovirus has been isolated from three cases. Diphtheria – Seventeen cases of diphtheria from seven different States were reported this week. No significant concentrations of cases are yet evident. The six cases from Georgia are from four separate counties.

Hepatitis - The number of hepatitis cases reported this week continues at approximately the same level as noted since last July. A summary of reported cases over and under 20 from the 17th through the 41st week appears on page 8. Only in the New England, Mid-Atlantic and Pacific districts are there States in which over 50 percent of reported cases are over the age of 20.

#### EPIDEMIOLOGICAL REPORT

#### Salmonella infantis Food Poisoning — Military Installation

On July 17 and 18, an outbreak of 65 cases of gastroenteritis occurred aboard a Navy vessel. Prompt intensive investigation revealed the probable vehicle to be roast turkey and the causative organism, Salmonella infantis.

The majority of those ill complained of diarrhea, cramps and anorexia; between 30 and 45% complained of headache, chills and fever, nausea and mralgia. Several were admitted to sick bay because of the severity of the symptoms.

Upon questioning, it was found that all of those ill were in the duty section on Sunday, July 16, and had eaten in General Mess. No selectivity by age, race, service rate or berthing area was apparent. Preliminary survey indicated the suspect meal to have been that served in the late afternoon. The average incubation period was slightly over 15 hours; 80 percent of the cases fell in the range of 10 to 24 hours.

The late afternoon meal had been served to 225 men and consisted of the following: roast turkey and dressing, potatoes, giblet gravy, cranberry sauce, peas, asparagus, lettuce-tomato salad with French dressing, bread, rolls, butter, milk and strawberry shortcake with whipped cream.

All of the 65 ill and 53 of those who remained asymptomatic were questioned regarding foods eaten and not eaten. Turkey appeared to be the most probable vehicle.

Attack Rates for Selected Foods According to History of Consumption

Food	Total Eating	No. Ill	% [1]	Total not Eating	No. Ill	% Ill

The chart shows the number of deaths reported for 117 major cities of the United States by week for the current year, a 5-week moving average of these figures plotted at the central week, and an adjusted average for comparison. For each region the adjusted average was computed as follows: From the total deaths reported each week for the years 1956-1960, 3 central figures were selected by eliminating the highest and lowest figure reported for that week. A 5-week moving average of the arithmetic mean of the 3 central figures was then computed with adjustment to allow for population growth in each region. The average value of the regional increases was 2 percent which was incorporated in the adjusted average shown in the chart.

Table 4 shows the number of death certificates re-

ceived during the week indicated for deaths that occurred in selected cities. Figures compiled in this way, by week of receipt, usually approximate closely the number of deaths occurring during the week. However, differences are to be expected because of variations in the interval between death and receipt of the certificate and because of incomplete reporting due to holidays or vacations. If a report is not received from a city in time to be included in the total for the current week, an estimate is used.

The number of deaths in cities of the same size may also differ because of variations in the age, race, and sex composition of the populations and because some cities are hospital centers serving the surrounding areas. Changes from year to year in the number of deaths may be due in part to population increases or decreases.

Table 3. DEATHS IN SELECTED CITIES BY GEOGRAPHIC DIVISIONS

(By place of occurrence and week of filing certificate. Excludes fetal deaths. Data exclude figures shown in parentheses in table 4)

Figures shown in parenthesis are from cities which have been reporting less than five years and hence are not included in Table 3.

The turkeys, supplied frozen by a North Carolina packer, were delivered to the installation on May 2. The boxes were unrefrigerated for 30 minutes before loading into the freezers. They remained in the freezers until July 15 when 16 turkeys were removed at 4:00 p.m. to a non-refrigerated space for thawing. The 16 birds, ranging from 20 to 25 lbs. in weight, remained in the non-refrigerated space until 7:00 a.m. on July '6 when they were put into the oven. However, the cook noticed that the "insides of the turkeys were still frozen solid" when they were placed in the oven. The birds were cooked from 7:00 a.m. until 1:00 p.m. at 300° F., removed from the oven to cool, and sliced at 2:00 p.m. The sliced turkey was then put directly on the line for serving. The cook stated the birds "looked good and tasted good."

No food remained from the suspect meal for laboratory study. However, rectal swabs were obtained from the 120 individuals interviewed. From 57, salmonella organisms of the C<sub>1</sub> group were obtained. All were serotyped as Salmonella infantis. Analysis of the results by those ill and not ill is presented below:

	No. Cultured	Positive for S. infantis	Percent Positive
111	65	38	58
Not ill	55	19	35
Total	120	57	48

In summary, the most likely mode of transmission would appear to have been via the visceral cavity and adjoining meat of the turkeys which were still frozen when placed in the oven and not cooked to a sufficient degree to kill the indigenous salmonella organisms.

(Reported by Lieutenant Stephen Kendra and Captain E. Siess, M.C., U.S. Navy, Preventive Medicine Unit No. 2. Norfolk, Virginia)
